(57) **ABSTRACT**

An assembly includes non-load bearing housings, each hous-  
ing including several cavities. Each cavity includes a stack of  
freely stacked electrochemical storage cells in the housings.  
Each electrochemical storage cell includes an anode elec-  
trode, a cathode electrode, and a separator located between  
the anode electrode and the cathode electrode. The assembly  
is configured such that pressure applied to the assembly is  
born by the freely stacked electrochemical storage cells.

# LARGE FORMAT ELECTROCHEMICAL ENERGY STORAGE DEVICE HOUSING AND MODULE

## FIELD

The present invention is directed to aqueous batteries and hybrid energy storage devices, and in particular to housings for such devices.

## BACKGROUND

Small renewable energy harvesting and power generation technologies (such as solar arrays, wind turbines, micro sterling engines, and solid oxide fuel cells) are proliferating, and there is a commensurate strong need for intermediate size secondary (rechargeable) energy storage capability. Batteries for these stationary applications typically store between 1 and 50 kWh of energy (depending on the application) and have historically been based on the lead-acid (Pb acid) chemistry. Banks of deep-cycle lead-acid cells are assembled at points of distributed power generation and are known to last 1 to 10 years depending on the typical duty cycle. While these cells function well enough to support this application, there are a number of problems associated with their use, including: heavy use of environmentally unclean lead and acids (it is estimated that the Pb-acid technology is responsible for the release of over 100,000 tons of Pb into the environment each year in the US alone), significant degradation of performance if held at intermediate state of charge or routinely cycled to deep levels of discharge, a need for routine servicing to maintain performance, and the implementation of a requisite recycling program. There is a strong desire to replace the Pb-acid chemistry as used by the automotive industry. Unfortunately the economics of alternative battery chemistries has made this a very unappealing option to date.

Despite all of the recent advances in battery technologies, there are still no low-cost, clean alternates to the Pb-acid chemistry. This is due in large part to the fact that Pb-acid batteries are remarkably inexpensive compared to other chemistries (\$200/kWh), and there is currently a focus on developing higher-energy systems for transportation applications (which are inherently significantly more expensive than Pb-acid batteries).

## SUMMARY

An embodiment relates to an assembly including a plurality of non-load bearing housings, each housing including a plurality of cavities. Each cavity includes a stack of freely stacked electrochemical storage cells in the housings. Each electrochemical storage cell includes an anode electrode, a cathode electrode and a separator located between the anode electrode and the cathode electrode. The assembly is configured such that pressure applied to the assembly is born by the freely stacked electrochemical storage cells.

Another embodiment relates to a method of making an assembly including a plurality of non-load bearing housings. Each housing includes a plurality of cavities. The method includes freely stacking anode electrodes, cathode electrodes and separators between the anode electrodes and the cathode electrodes in the plurality of cavities. The assembly is configured such that pressure applied to the assembly is born by the freely stacked electrochemical storage cells.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an exploded view of an electrochemical device according to an embodiment.

FIG. 24C is a schematic illustration of a detail of a sandwiched current collector according to an embodiment.

FIG. 25 is an exploded view of a stack of electrochemical cells with prismatic stacking.

FIG. 26A is a side cross sectional view of an electrochemical storage device according to an embodiment.

FIGS. 26B and 27 are respective top and bottom plan views of the embodiment device illustrated in FIG. 26A.

FIG. 26C is an exploded view of the housing and lid which enclose the electrochemical device of FIGS. 26A and 26B.

### DETAILED DESCRIPTION

Embodiments of the invention are drawn to electrochemical energy storage devices and systems, such as primary and secondary batteries and asymmetric/hybrid energy storage systems described below. While secondary hybrid aqueous energy storage devices described below are preferred embodiments of the invention, the invention is also applicable to any suitable electrochemical energy storage systems, such as aqueous and non-aqueous electrolyte containing batteries (e.g., having anodes and cathodes which intercalate ions from the electrolyte, including Li-ion batteries, etc.) or electrolytic capacitors (also known as supercapacitors and ultracapacitors, e.g., having capacitor or pseudocapacitor anode and cathode electrodes that store charge through a reversible non-faradaic reaction of cations on the surface of the electrode (double-layer) and/or pseudocapacitance rather than by intercalating alkali ions).

Hybrid electrochemical energy storage devices and systems of embodiments of the present invention include a double-layer capacitor or pseudocapacitor electrode (e.g., anode) coupled with an active electrode (e.g., cathode). Such devices are also known as asymmetric electrochemical energy storage devices. In these systems, the capacitor or pseudocapacitor electrode stores charge through a reversible nonfaradaic reaction of alkali cations on the surface of the electrode (double-layer) and/or pseudocapacitance, while the active electrode undergoes a reversible faradaic reaction in a transition metal oxide that intercalates and deintercalates alkali cations similar to that of a battery, such as those described in U.S. patent application Ser. No. 13/043,787 filed on Mar. 9, 2011 and incorporated herein by reference in its entirety.

In an alternative embodiment, the electrochemical energy storage device comprises a battery in which both the anode electrode and the cathode electrode are made of materials that intercalate ions. For example, the battery may be a sodium or lithium ion based battery which includes a graphite anode and a metal oxide containing cathode, such as a layered oxide, e.g., lithium cobalt oxide, or a polyanion, e.g., lithium iron phosphate, or a spinel, e.g., manganese oxide, for example a doped or undoped cubic spinel  $\lambda$ - $\text{MnO}_2$ -type material that intercalates lithium or sodium ions, or a  $\text{NaMn}_2\text{O}_{1.8}$  tunnel structured orthorhombic material. In another alternative embodiment, the anode electrode is made of a mixture of materials, one of which intercalates ions (e.g., sodium or lithium) in a faradaic reaction and the other one of which is a capacitive electrode material which stores charge through the reversible nonfaradaic reaction of alkali metal cations on a surface of the anode electrode or the pseudocapacitive electrode material which undergoes a partial charge transfer surface interaction with alkali metal cations on a surface of the anode electrode. An example of such a mixed anode material is a mixture of "faradaic" graphite and "nonfaradaic" active amorphous or polycrystalline carbon.

4

Embodiments include configurations of and packaging for a manufacturable large-scale electrochemical energy storage device. Specifically, there is a need to develop a new way of containing the electrochemical energy storage device cells that is both economically feasible and high performing. Embodiments include the individual building block unit housing comprising outer walls and an integral base wall formed to include cavities separated by partitions which are preferably integral with the outer walls and base wall and a lid which may be separable from the housing or attached to the housing e.g., by a hinge or the like. Individual building block unit housings include a 4-cavity configuration, each cavity containing an electrochemical energy storage device connected in series or parallel in a square "2 by 2" format. Alternative units may have more or less cavities and may be arranged in other configurations, such as 1 by 2, 1 by 3, 1 by 4, 2 by 3, 2 by 4, 3 by 4, etc. Embodiments also include a module, which is a stack of these units stacked on top of each other. The housings and lids may be made of a polymer, such as polypropylene.

Design considerations for the embodiments discussed below include the electrochemistry and electrode materials. In an embodiment, the electrodes (anode, cathode or both anode and cathode) are made from free standing pressed pellets. In an embodiment, electrochemical energy storage device is made by stacking the pellets into the housing in the proper order (e.g., current collector, cathode, separator, anode, current collector, anode, separator, cathode, and repeat). Each of the cavities in the electrochemical energy storage device may have many cells like this connected in parallel to make, for example, a 0 to 2.5 V electrochemical energy storage device. In an embodiment, each stack may then be connected in series. For a four cavity device, the device may be a 0 to 10 V system.

The housing lids may be hot plate sealed to the housing after assembly. The lid to housing interface may also be laser-sealed, sealed with adhesives, or sealed using a compression force and some type of polymeric gasketing. In an embodiment, the housing has a single pressure relief valve. Preferably, the cavities have small airways connecting them such that any excess gas that evolves anywhere in the electrochemical energy storage device can be released by the pressure relief valve. The electrical connections between stacks disposed in individual cavities of unit may be described as "jumpers" and they are formed by either directly spot welding current collection tabs together, or via a metal pass-through between the cavities. Typically, the jumpers are metal, such as stainless steel, although Al, and/or Al/stainless clad structures may also be used. Other conductive materials may also be used.

An aspect of the embodiments below is that the electrode stacks disposed inside respective individual cavities of the housings are placed in mating contact with each other by an externally applied pressure or compression force tending to compress the stacks. Absent this pressure, the electronic integrity of individual stacks of the electrochemical energy storage device may suffer and performance may be sub-standard. In particular the pressure or compression force applied to each stack places adjacent stack elements in mating contact thereby decreasing the gap between adjacent elements which tends to increase ion exchange between the anodes, the cathodes and the electrolyte present in the gap between them, as well as to increase current flow from the anodes and cathode to the adjacent current collectors. In an embodiment, the electrochemical energy storage device units (i.e., housings containing the storage device stacks) include a hole in their center to provide for a tie bar that can go through a plurality of

5

the units stacked together in an assembly and attach to two opposing rigid plates with one positioned at a top of the units stacked together and the other positioned at a bottom of the units stacked together to thereby apply a compression force to the stacked together units when the tie bar is placed into a condition of tension. Moreover, the pressure plates are configured to transfer the tension force applied to the tie bar directly to the electrode stack. Optionally, a semi-rigid body may be used to provide “spring force” on the top of the electrochemical energy storage device stack such that there is some room for electrode stack breathing during use. These stacks of electrochemical energy storage devices can then be connected in series or parallel as needed. Also, in an embodiment, stacks of electrochemical energy storage devices can be fitted onto pallet structures with integrated electronic controls and power lines to form modules. These modules can then be stacked integrated into larger systems. To allow for the facile translation of pressure from outside the case to the electrode stack, a completely flexible battery lid may be used.

Embodiments may include one or more of the following features as well as other features as described above and illustrated in the attached figures:

- 1) a single tie rod through the middle of the electrochemical energy storage device stack housing used to keep a stacks together,
- 2) the electrochemical energy storage device units (i.e., housings) are designed such that the electrode stacks inside them bear the load of the pressure imparted on the stack by the tie rod,
- 3) a mildly elastic member may be used as a “spring force” to maintain long term positive pressure on the stacks,
- 4) the housings may be assembled onto pallets with integrated electronic controls and power lines,
- 5) inside the electrochemical energy storage device housing, there may be single pressure relief valve and the electrochemical energy storage devices in the cavities may then be connected in series or parallel,
- 6) There may be an open gas pathway between the cavities, and
- 7) The electrochemical energy storage device cavities may be filled with a gelled liquid electrolyte (or gelled water) as a source of moisture for the electrode stacks that will not “slosh” around and affect performance.

FIGS. 1, 2 and 4 illustrate an electrochemical device 100 according to a first embodiment. As illustrated, the electrochemical device 100 includes a housing 102 that includes four cavities 104. As discussed above, the housing 102 may have more or fewer than four cavities 104. Each cavity is defined by walls 105 of the housing 102. In the embodiment illustrated in FIGS. 1, 2 and 4, each cavity 104 is bounded by two external walls 105 (walls that have a face on the periphery of the electrochemical device 100) and two internal walls or partitions 105 (walls located on the inside of the electrochemical device 100). In alternative configurations, the cavities 104 may have more or less than two external and two internal walls 105. For example, in a 3 by 3 configuration, the central cavity 104 is entirely bounded by internal walls or partitions 105, side cavities 104 (not in the corner) are bounded by one external wall and three internal walls, while the corner cavities 104 are bounded by two internal walls and two external walls. In a 1 by 3 configuration, the center cavity 104 is bounded by two internal and two external walls 105 while the two end cavities 104 are bounded by one internal wall 105 and three external walls 105.

Preferably, each cavity 104 includes a stack 110 of electrochemical cells 111. Each electrochemical cell 111 includes an anode 112, a cathode 114 and a separator 116 located

6

between the anode 112 and the cathode 114. In further embodiments a hybrid or asymmetric electrochemical cell 111 may include a second anode and a second cathode separated by a second separator. The electrochemical cells 111 may be electrically connected in series or prismatically in the stack 110 of electrochemical cells 111. In a prismatic configuration, the electrochemical cells 111 in the stack 110 are connected in parallel as illustrated in FIG. 25.

Each electrochemical cell 111 further includes two current collectors 130, 132 provided to collect the current generated by the electrochemical cells 111. The current collectors 130, 132 may be made of any suitable electrically conducting material, such as carbon (e.g. graphite) or metal. In a prismatic stack 110, described for example in U.S. patent application Ser. No. 13/043,787 and illustrated in FIG. 25, pairs of electrochemical cells 102 are configured “front-to-front” and “back-to-back.” The cathode current collector 130 may be located in between cathodes 114 of adjacent electrochemical cells 111. As an example, consider a prismatic stack 110 in which the first electrochemical cell 111 is in the center of the stack 110. In a first pair of cells 111 the first cathode current collector 130 is located such that a cathode electrode 114 of the first electrochemical cell 111 electrically contacts the first cathode current collector 130 and a cathode electrode 114 of a second electrochemical cell 111 also electrically contacts the first cathode current collector 130. The second electrochemical cell 111 is located adjacent to a first (cathode) side of the first electrochemical cell 111 in the prismatic stack 110.

A third electrochemical cell 111 is located adjacent to the second (anode) side of the first electrochemical cell 111 in the prismatic stack 110. The anode electrode 112 of the first electrochemical cell 111 electrically contacts a first anode current collector 132 and the anode electrode 112 of the third electrochemical cell 111 also electrically contacts the first anode current collector 132. Stacking can continue in this manner. The resulting prismatic stack 110 therefore may include a plurality of electrochemical cells 111 that are stacked in pairs, front-to-front and back-to-back, alternating adjacent anode electrodes 112 and adjacent cathode electrodes 114.

Preferably, the anodes 112, cathodes 114, separators 116 and current collectors 130, 132 are freely stacked and are not laminated to each other in the cavities 104. That is, no adhesives or binders are located between the individual components (anodes 112, cathodes 114, separators 116 and current collectors 130, 132) in the stacks 110 as are typically found in conventional laminated electrochemical cells. Instead, one embodiment of the present invention applies a longitudinal pressure force to a plurality of freely stacked electrochemical cells that forces adjacent cell elements into mating contact to improve the electrochemical reaction between the anodes and cathodes and the electrolyte that fills the cavities as well as to improve electrical contact between the current collectors corresponding anodes and cathodes to increase current flow to the current collectors.

Another embodiment is illustrated in FIGS. 24A and 24B. In this embodiment, a stack 110 of electrochemical cells is located in a cavity 104 of a housing 102 as in previous embodiments. In contrast to previous embodiments, the anode electrode 112 and/or the cathode electrode 114 may be made of two or more discrete pieces, such as 4, 6, 9 or any number of discrete pieces. As illustrated in FIG. 24B, the cathode electrode 114 includes 4 discrete pieces. In an embodiment, the area of the cathode current collector 130 when viewed from above is greater than the area of the cathode electrode pieces 114. Similarly, the area of the anode

current collector **132** when viewed from above may be greater than the area of the anode electrode pieces **112**.

In an aspect of this embodiment, the separator **116** includes flanges **116A** around the periphery of the separator **116**. The flanges **116A** define one or more cavities that are configured to receive the anode/cathode electrode pieces **112**, **114**. In another aspect, the electrochemical storage cells **111** include a plurality of flexible, electrically conductive contacts (e.g., tabs) **118** operatively connected to the plurality of cathode and anode current collectors **130**, **132**. The flexible, electrically conductive contacts **118** may be affixed to one side of the cathode and anode current collectors **130**, **132**. In this embodiment, electrical connection to the stacks **110** of electrochemical storage cells **111** in adjacent cavities **104** in the housing **102** may be made by draping the flexible, electrically conductive contacts **118** over the walls **105** between adjacent cavities **104** and connecting the stacks **110**. The stacks **110** in adjacent cavities **104** may be electrically connected in series, in parallel or combination thereof as desired. In the embodiment illustrated in FIG. 26A, discussed in more detail below, the flexible, electrically conductive contacts **118** from adjacent stacks **110** are joined together **166**, such as by welding or brazing.

In an embodiment, the stack **110** of electrochemical storage cells **111** is prismatically stacked. A plurality of electrically conductive contacts (e.g., tabs) **118** operatively connected to the plurality of cathode and anode current collectors **130**, **132**. As in the previous embodiments, the electrically conductive contacts **118** may be affixed to one side of the cathode and anode current collectors **130**, **132** as shown in FIG. 25. Alternatively, as illustrated in FIG. 24C, the electrically conductive contacts **118** may be located in between two current collectors **130** or **132** of the same type, making a sandwich structure **131**.

In an embodiment, the electrically conductive contacts **118** of alternate cells **111** in the stack **110** of cells **111** are affixed to each other, such as by welding or brazing. That is, the electrically conductive contacts **118** connected to successive cathode electrodes **114**/cathode current collectors **130** are connected to each other while the electrically conductive contacts **118** connected to successive anode electrodes **112**/anode current collectors **132** are connected to each other. In this manner, the electrochemical cells **111** in the stack **110** can be electrically connected in parallel.

FIGS. 26A and 26B illustrate an embodiment of an electrochemical device **100** having four adjacent stacks **110** configured in a 2x2 pattern in a housing having four cavities **104** in the 2x2 pattern. As illustrated in FIG. 26B, the adjacent stacks **110** are electrically connected in series. Alternatively, adjacent stacks may be electrically connected in parallel. As discussed above, the electrical connection between adjacent stacks **110** may be made by joining the flexible, electrically conductive contacts **118** of the cell **111** of the adjacent stacks **110**, such as by welding or brazing at locations **166** on top of the interior walls **105** of the housing **102**. FIG. 26C is an exploded view of the housing **102** and lid **106** (with the lid removed from the housing) which enclose the stacks shown in FIGS. 26A and 26B.

In an alternative embodiment shown in FIG. 25, the prismatic stack **110** also includes two electrical buses **134**, **136**. One electrical bus **134** electrically connected to the anode current collectors **132** in the prismatic stack **110** and one electrical bus connected **136** to the cathode current collectors **130** in the prismatic stack **110**. In an embodiment, the electrical connection from the cathode and anode current collectors **130**, **132** to the electrical buses **134**, **136** is via the elec-

trically conductive contacts **118**. In this manner, the electrochemical cells **111** in the stack **110** can be electrically connected in parallel.

The electrochemical device **100** also includes a liquid or gel electrolyte (not shown) in the cavities **104** which substantially fills the cavity to immerse each electrochemical cell in electrolyte. The housing **102** of the electrochemical device **100** is preferably hermitically sealed with a lid **106** to prevent the loss of electrolyte from the electrochemical device **100** and a common gas volume is provided above each cavity between the top of each cavity and the lid to allow outgassing from all of the cavities to collect in the gas volume. In an embodiment, the lid **106** includes a hole **160** in the center which is aligned with a corresponding hole **161** that extends through the housing **102** for receiving the tie rod **206** there through. The lid **106** may also include lid cavities **107** which are recessed to ensure that a bottom surface of each cavity **107** contacts the top surface of the electrode stack in the corresponding cavity in order to transfer a pressure or compression force from pressure plates **202** through each unit in an assembly **200** when the units are stacked in an assembly, as shown in FIG. 6. As discussed in more detail below, the lid cavities **107** are preferably configured to facilitate stacking of electrochemical devices **100** in a manner that transfer the above described pressure force from one unit device to another. The housing **102** may include features to hold terminals **133** that may be connected to an outside load or to other electrochemical devices **100** as discussed in more detail below.

As illustrated in FIG. 4, the cavities **104** may be fluidly connected to each other via holes **120** in the inside walls **105** in the housing **102** forming the cavities **104**. The lid **106** may include a pressure relief valve **124** configured to release gas in the event of excess gas build up during operation of the electrochemical device **100**. Because all of the cavities **104** are fluidly connected via the holes **120**, the lid **106** may have only a single pressure relief valve **124** for all cavities **104** in the housing **102**. Also illustrated in FIG. 4 are flexible electrical connectors **118** (e.g. stainless steel or another metal) electrically connecting the electrochemical stacks **110** of a first cavity **104** with a second cavity **104** in the housing **102** of the electrochemical device **100**. All of the cavities **104** in the electrochemical device **100** may be similarly connected to each other as shown in FIG. 26. The flexible electrical connectors **118** may be configured such that stacks **110** of electrochemical cells **111** within the electrochemical device **100** are in series or in parallel or a combination thereof. Additionally, the electrochemical device **100** includes at least one electrolyte port **162** in the lid **106**. Electrolyte may be added to the electrochemical device **100** via the electrolyte ports **162**. The electrolyte ports **162** may be covered with caps **163** to prevent spillage of electrolyte out of the electrolyte ports **162**.

In a method of making the electrochemical device **100**, the lid **106** is sealed onto the housing **102** after the solid components (e.g. the anode electrodes **112**, cathode electrodes **114**, separators **116**, anode current collectors **132** and cathode current collectors **130**) are stacked in the housing **102**. Then, the device **100** is evacuated via the electrolyte ports **162** to remove any undesired gases. After evacuation, the cavities **104** of the electrochemical device **100** are partially filled with electrolyte, leaving a gas space or volume above the electrolyte in the cavities **104**.

FIGS. 3 and 5-9B illustrate an assembly **200** comprising a plurality of (e.g. a stack) of electrochemical device units **100** stacked one above another according to another embodiment. As illustrated in FIG. 3, the housings **102** and lids **106** of the electrochemical device units **100** are configured such that the

electrochemical device units **100** can be stably stacked upon each other. That is, the lid cavities **107** are dimensioned to receive the bottom surface and the bottom parts of the walls **105** of the cavities **104** of the housing **102** of the electrochemical device unit **100** stacked on top.

As illustrated in FIG. 5, in an embodiment, the electrochemical unit **100** may include one or more pass through electrical connectors **140**, e.g., one connector **140** associated with each terminal **133** shown in FIG. 26B or with each power bus **134**, **136** shown in FIG. 25. The pass through electrical connector **140** is a vertically oriented (i.e., it has a longitudinal axis parallel to the stacking direction) electrically conducting structure, e.g., the male portion of a standard electrical power connector molded into the housing, but other orientations and or locations are usable without deviating from the present invention. Alternately the connector **140** may comprise the female portion of a standard electrical power connector molded into the housing. Otherwise the connector **140** may comprise electrical elements molded into the housing or installed in the housing that are configured to mate with the male or female portion of a power connector to electrically interconnect the electrochemical device unit **100** to another electrochemical device unit **100** or a power load as may be the case. Accordingly the stacks **110** of electrochemical cells **111** housed within the electrochemical device unit **100** can be electrically connected with other electrical elements using one or more terminals **133** described above by an electrical connector **140**. In an embodiment, the pass through connectors **140** of each of the electrochemical device units **100** in the assembly **200** are electrically connected to the pass through connectors of the adjacent electrochemical device units **100** in the assembly **200** to either charge or discharge the entire assembly **200** as a unit. These connections may be made in series or in parallel and alternatively can be made of, such as with wires **141** affixed to the terminals **133** or connectors **140** as shown in FIG. 6.

The pass through connectors **140**/terminals **133** are located within the housing **102** and therefore protected by the housing **102**. That is, the housing **102** provides a "shroud" **143** surrounding the vertically oriented pass through connectors **140**/terminals **133** which protect the pass through connectors **140**/terminals **133** and the underlying electrochemical devices **100** during handling of the assembly **200**. In contrast, the use of horizontal, i.e. protruding, terminals may risk puncture with adjacent electrochemical cells **100** during handling of the assembly **200**. In an embodiment, the pass through connector **140** is held in place with a push retainer **142**. To protect the housing **102** and further secure the push retainer **142**, a washer **144**, such as a flat washer or lock washer, may be provided on one side of the housing **102**, and a seal **146**, such as a silicone rubber seal, may be provided on the other side of the housing **102**.

The assembly **200**, as illustrated in FIG. 6, may include pressure plates **202** at the top and bottom of the stack of electrochemical devices **100**. In an embodiment, the pressure plates **202** at the top and the bottom of the stack of electrochemical devices are identical, which simplifies assembly and may save on costs. The pressure plates **202** may have free standing feet **204** which provide space between the pressure plates **202** and adjacent structures such as a support pallet and/or module lid discussed in more detail below. The pressure plates **202** may also include a through hole **203** (see FIG. 9A) configured to accept a binding member **206**, discussed in more detail below, and flanges **205** configured to help center the electrochemical devices **100** on the pressure plates **202**. The pressure plates **202** may also include ribs **201** for added

strength and to aid in aligning the pressure plates to apply a pressure load at the desired locations.

As discussed above, the components of the electrochemical cells **111** are freely stacked. However, the inventors have discovered that the electrochemical devices **100** are more robust when the stacks **110** of electrochemical cells **111** are under pressure. Therefore, as discussed in more detail below, assemblies **200** of electrochemical devices **100** are configured such that the stacks **110** of electrochemical cells **111** are assembled such that the cells **111** are under pressure. Preferably, the stacks **110** bear most or all (e.g. at least 90%, such as 90-100%, e.g. 95-99%) of the compressive loading. That is, it is preferable that the housings **102** and the lids **106** bear little or no compressive loading (e.g. 0-10%, such as 1-5%). That is, the housing **102** and the lid **106** are made of a flexible material (e.g. plastic, such as polypropylene) that bends or otherwise plastically deforms under a pressure/load applied by the pressure plates and the weight of the electrochemical device units stacked one above another.

One or more elastic elements **208** may be provided between the pressure plates **202** and the electrochemical devices **100** in the assembly **200**. Elastic elements **208** (see FIGS. 6, 7A, 7B and 7C) may be provided between the bottom pressure plate **202** and the stack of electrochemical devices **100**, between the top pressure plate **202** and the stack of electrochemical devices **100** or between both pressure plates **202** and the stack of electrochemical devices **100**. The elastic element **208** may be made of a springy material, such as silicone or rubber.

A binding member **206** (such as the tie rod illustrated in FIG. 7C, a cable or a spring), may be provided through the holes **160** in the lids **106** and holes **161** in the housings **102** of the electrochemical devices **100**. The binding member **206** also passes through the pressure plates **202** (FIGS. 8A-8C). The binding member **206** may be secured to the pressure plates with tightening/securing members **207**, such as a nut installed on a threaded end of the binding member **206** or the like tension the binding member **206**. The tension in the binding member is used to force each pressure plate into mating contact with the corresponding top and bottom electrochemical units **100** or the assembly or stack **200**. Thus tension in the binding member **206** is transferred to the pressure plates **202** which transfer the pressure force to the top and bottom electrochemical device units **100** in the assembly **200** which in turn transfer the pressure force to each of the remaining electrochemical device units **100** in the assembly **200**. More specifically, the pressure plates **202**, the housing bottom surfaces **420** shown in FIG. 27 and lid cavities **107** are configured to align and interlock the units **100** and to transfer the pressure force applied to the pressure plates directly to the electrode stacks in each cavity such that tensioning the binding member **206** applies a compression force to each of the electrode stacks included in the assembly **200**. Pressure may be applied to the assembly **200** by tightening the tightening/securing members **207**, thereby causing the pressure plates to apply pressure or clamping force to the stack of electrochemical devices **100** in the assembly **200**. When one or more elastic elements **208** are included in the stack, the elastic elements **208** deform in response to the pressure force and tend to more uniformly distribute the pressure load over the bearing surfaces, specifically the lid cavities **107** and the housing bottom surfaces **420** and to more uniformly distribute the pressure force to each of the four load bearing surfaces of the lid cavities **107** and the bottom bearing surfaces **420**. In an alternative embodiment, the binding member **206** has a fixed length and the pressure or clamping force is determined by the thickness of the elastic element(s) **208**. Alternately the bind-

11

ing member **206** has a fixed length and the pressure or clamping force is applied by one or more compression springs disposed between the opposing pressure plates **202**. A removable eye nut **210** may be affixed to the top of the binding member **206** to assist in lifting and otherwise handling the assembly **200**.

FIG. **8A** illustrates some dimensions that may be used to characterize the assembly **200**. The distance **208x** represents the thickness of the elastic element **208** (non-deflected). The distance **207x** is measured from the bottom of a non-deflected elastic element **208** to the top of the bottom pressure plate **202**. The distance **206x** is the distance between the top and bottom pressure plates **202**. In various embodiments the pressure force applied may be proportional to ratio of the thickness of non-deflected and the thickness of the elastic member element **208** after a pressure force is applied, i.e. the deflected thickness.

FIG. **10** illustrates a module **300** of assemblies **200** according to an embodiment. In this embodiment, assemblies **200** are mounted on a base, such as a pallet **302**. As illustrated, the module **300** may include twelve assemblies **200** in a 3 by 4 configuration. However, the module **300** may include any number of assemblies **200**, such as 1 by 2, 1 by 3, 1 by 4, 2 by 3, 2 by 4, 3 by 5, etc. The module **300** preferably includes a module lid assembly **306**, discussed in more detail below and a guard **308** that surrounds and protects the assemblies **200**.

FIG. **11** illustrates an embodiment of a module **300** with the lid assembly removed. Adjacent assemblies **200** may be mechanically clamped to each other with one or more mechanical stack connectors **310**, illustrated in more detail in FIG. **12**. In an embodiment, the stack connectors **310** are affixed to adjacent pressure plates **202**.

FIG. **13** illustrates a cross section through a module **300**. The module **300** includes a module frame **303** located on a pallet **302**. Frame **303** is configured to receive the assemblies **200**. That is, the module frame **303** includes trenches to receive the feet **204** and the ribs **201** of the pressure plates **202** and thereby provide a more stable support for the assemblies **200**. The module **300** also includes an actuator/push rod **312** and a module to module connector **314**, for mechanically attaching modules together, as described in more detail below. The actuator/push rod **312** and module to module connector **314** allow adjacent modules **300** to be mechanically connected together to form an integrated electrochemical storage system comprising a plurality of electrochemical assemblies **200**.

FIGS. **14-18** illustrate details of a lid assembly **306** for a module **300** according to an embodiment. In an embodiment, the lid assembly **306** includes a cover **307** and a lid assembly frame **316** (FIG. **15**). The lid assembly frame **316** includes one or more space protectors **318** and contactors **320** which make physical connection with the lid assembly cover **307** of the module lid assembly **306** and aid in properly seating the lid assembly cover **307** on the lid assembly frame **316**. FIG. **15** also illustrates the placement of the actuator rod **312** in the assembly frame **316** of the lid assembly **306**.

FIG. **16** illustrates top and bottom views of the lid assembly **306**. As illustrated in FIG. **16**, the lid assembly **306** includes recesses **317** configured to receive pressure plates **202** of individual assemblies **200** therein. FIG. **16** also illustrates the placement of the actuator rod **312**, module to module connector **314**, stack connectors **310**, space protectors **318** and contactors **320**.

FIGS. **17A**, **17B** and **18** provide details of a method of connecting modules with the mechanical module to module connector **314**. The mechanical module to module connector **314** includes male plug locator **326** and two connector pins

12

**322**. The connector pins **322** are attached to the ends of connector blocks **324**. In alternative embodiments, more or fewer connector pins **322** are used. The connector blocks **324** are operably connected to the actuator/push rod **312**. In an embodiment, after all modules **300** are in place and aligned, a cam or protrusion (not shown) on the container door (not shown) contacts the last actuator/push rod **312** and all the connectors **314** are shuttled to the left (as illustrated), causing the connector pins **322** on one module to engage the female receptacles **323** on an adjacent module. FIG. **18**, illustrates the male locating plug **326** on one module approaching the female locating socket **328**. When these features are fully engaged and the modules **300** are positioned end to end, the actuator/push rod **312** is actuated, forcing the connector blocks **324** and connector pins **322** into the female receptacles **323**.

FIGS. **19-21** illustrate details of an embodiment of a pallet assembly **302** for use with a module **300**. In this embodiment, the pallet assembly **302** includes a pan **329** and a nest tray **330** located on the pan **329**. The pan **329** and the nest tray **330** may be made of any suitable material, such as polyethylene. The nest tray includes recesses **317** configured to receive pressure plates **202** while the pan **329** includes fork tunnels **334** (FIG. **20A**) configured to receive the forks of a fork lift truck. As illustrated in FIGS. **20A** and **20B**, the nest tray **330** also includes reinforcing structures **332** (e.g. steel bars, rods, plastic flanges etc.) to strengthen the nest tray **330** and to stabilize the modules **300**. The reinforcing structures **332** may be provided in both lateral and longitudinal orientations to strengthen the nest tray **330**.

FIGS. **22A-22C** illustrate a guard **308** for a module according to an embodiment. In an embodiment, the guard **308** is a perforated enclosure made of steel, such as perforated 16 gauge steel. However, the guard **308** may be made of any suitable material. The guard **308** may be assembled in sections. In an embodiment, adjacent sections of the guard **308** are attached to each other with a guard interlock channel **309** (FIG. **22C**). The guard **308** may be affixed to the nest tray **330** by inserting a portion of the guard into a slot **336** in the nest tray **330** (FIG. **22B**).

FIGS. **23A** and **23B** are electrical circuit diagrams that illustrate the internal **338** assembly **200** electrical connections in each module **300** and external **340** inter-module **300** electrical connections. The electrical connections may be located in a module lid assembly **306** and/or in a pallet assembly **302**, respectively, according to an embodiment. As illustrated in FIG. **23A**, the module lid assembly **306** may include both internal and external electrical connections **338**, **340**. In this embodiment, the module **300** on the pallet assembly **302** only includes internal electrical connections **338** between the assemblies. In alternative embodiments, the pallet assembly **302** includes internal and external electrical connections **338**, **340** while the module lid assembly includes only internal electrical connections **338**. In other embodiments, both the module lid assembly **306** and the pallet assembly **302** include internal and external electrical connections **338**, **340**.

In the embodiment illustrated in FIG. **23B**, the electrochemical devices **100** are connected in series in the assembly **200**. Only one assembly **200** and one connector **342** are illustrated for clarity. In an embodiment, each connector **342A** may connect four assemblies **200** in series. The module **300** may include three connectors **342A** for 12 assemblies. The module lid assembly **306** includes 3 mating connectors **342B**, each of which may be electrically connected a respective assembly **200** connector **342A**. In this embodiment, the module **300** may include total of 12 assemblies **200**. However, as discussed above, the modules **300** may include more

## 13

or fewer assemblies 200 than 12 and may include more or fewer connectors 342. Further, the connectors 342A, 342B with four electrical connections are for illustration only. Other connectors 342 with more of fewer electrical connections may be used as well. Connectors 342A, 342B may include, but are not limited to, Anderson Power Products Blind Mate series BMHSG-R and -P type connectors or other similar connectors. The pallet assembly 302 may contain charge control/power electronics for charging each module 300 as a whole or for charging individual assemblies 200 or for charging individual electrochemical device units 100 or a combination thereof.

The assemblies 200 in the module may be connected together either in series or in parallel, depending on the desired use of the module 300. The series/parallel connections may be located in either the module lid assembly 306 or the pallet assembly 302. If the series/parallel connections are provided in the module lid assembly 306, then the module 300 can be easily reconfigured by simply replacing a first module lid assembly 306 with one connection configuration with a second module lid assembly 306 having a different connection configuration. In one example, as illustrated in FIGS. 23A and 23B, the assemblies 200 are connected in parallel via connectors 342A in the pallet assembly 302 while the modules 300 are connect to each other in series via the lid 106.

Although the foregoing refers to particular preferred embodiments, it will be understood that the invention is not so limited. It will occur to those of ordinary skill in the art that various modifications may be made to the disclosed embodiments and that such modifications are intended to be within the scope of the invention. All of the publications, patent applications and patents cited herein are incorporated herein by reference in their entirety.

What is claimed is:

1. An energy storage assembly, comprising:
  - a plurality of electrochemical device units stacked one above another between opposing pressure plates;
  - wherein each of the plurality of electrochemical device units comprises a housing and a lid forming a plurality of cell cavities with each of the plurality of cell cavities filled with a plurality of electrochemical storage cells, wherein each of the plurality of electrochemical storage cells comprises:
    - an anode electrode;
    - a cathode electrode; and
    - a separator located between the anode electrode and the cathode electrode; and
  - wherein each of the housing and the lid comprises non-load bearing opposing external surfaces of each cell cavity; and
  - a binding member interconnecting the opposing pressure plates;
  - wherein when the binding member is placed in a condition of tension, the non-load bearing opposing external surfaces of each cell cavity impart a pressure to each the plurality of electrochemical storage cells such that the storage cells bear a load of the pressure;
  - wherein the anode and cathode electrodes of the electrochemical storage cells bear at least 90 percent of the loads applied to the energy storage assembly.
2. The assembly of claim 1, wherein each of the plurality of electrochemical cells further comprises:
  - an anode current collector disposed to collect current from the anode electrode of each of the plurality of electrochemical storage cells; and

## 14

a cathode current collector disposed to collect current from the cathode electrode of each of the plurality of electrochemical storage cells.

3. The assembly of claim 2, further comprising:
  - first electrically conductive contacts connecting a plurality of the anode current collectors; and
  - second electrically conductive contacts connecting a plurality of the cathode current collectors.
4. The assembly of claim 3, wherein the storage cells are electrically connected in parallel and configured in a prismatic configuration.
5. The assembly of claim 3, wherein:
  - the first electrically conductive contacts are joined together and electrically connected to a positive terminal exposed outside of the housing and the second electrically conductive contacts are joined together and electrically connected to a negative terminal exposed outside of the housing; and
  - the first and the second electrically conductive contacts comprise flexible electrically conductive contacts which electrically connect stacks of the storage cells located adjacent to the cell cavities by extending over the walls between the adjacent cell cavities.
6. The assembly of claim 1, wherein the plurality of the electrochemical storage cells comprise hybrid devices.
7. The assembly of claim 6, wherein the cathode electrode comprises an alkali ion intercalation material and the anode electrode comprises a pseudocapacitive or electrochemical double layer capacitive material.
8. The assembly of claim 6, wherein the anode electrode comprises a mixture of materials one of which intercalates ions in a faradaic reaction and the other one of which is a pseudocapacitive or electrochemical double layer capacitive material.
9. The assembly of claim 1, wherein the plurality of electrochemical storage cells comprise battery cells in which the anode electrode and the cathode electrode intercalate ions.
10. The assembly of claim 1, wherein:
  - the opposing pressure plates comprises upper and lower opposing pressure plates;
  - the plurality electrochemical device units are stacked one above another between the opposing upper and lower pressure plates;
  - each of the housing and the lid comprises non-load bearing opposing external surfaces located above and below of each cell cavity; and
  - the binding member comprises a rod which extends through holes in the upper pressure plate, in the housing and the lid of each of the plurality of electrochemical device units, and in the lower pressure plate.
11. A method of making an energy storage assembly, comprising:
  - providing a plurality of electrochemical device units comprising a housing and a lid forming a plurality of cell cavities with each of the plurality of cell cavities filled with a plurality of electrochemical storage cells;
  - wherein:
    - each of the plurality of electrochemical storage cells comprises:
      - an anode electrode;
      - a cathode electrode; and
      - a separator located between the anode electrode and the cathode electrode; and
    - each of the housing and the lid comprises non-load bearing opposing external surfaces of each cell cavity;
  - stacking the plurality electrochemical device units between opposing pressure plates;

## 15

interconnecting the opposing pressure plates with a binding member; and

placing the binding member in a condition of tension such that the non-load bearing opposing external surfaces of each cell cavity impart a pressure to each the plurality of electrochemical storage cells such that the storage cells bear a load of the pressure;

wherein the anode and cathode electrodes of the electrochemical storage cells bear at least 90 percent of the loads applied to the energy storage assembly.

12. The method of claim 11, wherein each of the plurality of electrochemical cells further comprises:

an anode current collector disposed to collect current from the anode electrode of each of the plurality of electrochemical storage cells; and

a cathode current collector disposed to collect current from the cathode electrode of each of the plurality of electrochemical storage cells.

13. The method of claim 12, further comprising:

first electrically conductive contacts connecting a plurality of the anode current collectors; and

second electrically conductive contacts connecting a plurality of the cathode current collectors.

14. The method of claim 13, wherein the storage cells are electrically connected in parallel and configured in a prismatic configuration.

15. The method of claim 13, wherein:

the first electrically conductive contacts are joined together and electrically connected to a positive terminal exposed outside of the housing and the second electrically conductive contacts are joined together and electrically connected in series to a negative terminal exposed outside of the housing; and

## 16

the first and the second electrically conductive contacts comprise flexible electrically conductive contacts which electrically connect stacks of the storage cells located adjacent to the cell cavities by extending over the walls between the adjacent cell cavities.

16. The method of claim 11, wherein the plurality of the electrochemical storage cells comprise hybrid devices.

17. The method of claim 16, wherein the cathode electrode comprises an alkali ion intercalation material and the anode electrode comprises a pseudocapacitive or electrochemical double layer capacitive material.

18. The method of claim 16, wherein the anode electrode comprises a mixture of materials one of which intercalates ions in a faradaic reaction and the other one of which is a pseudocapacitive or electrochemical double layer capacitive material.

19. The method of claim 11, wherein the plurality of electrochemical storage cells comprise battery cells in which the anode electrode and the cathode electrode intercalate ions.

20. The method of claim 11, wherein:

the opposing pressure plates comprises upper and lower opposing pressure plates;

the plurality electrochemical device units are stacked one above another between the opposing upper and lower pressure plates;

each of the housing and the lid comprises non-load bearing opposing external surfaces located above and below of each cell cavity; and

the binding member comprises a rod which extends through holes in the upper pressure plate, in the housing and the lid of each of the plurality of electrochemical device units, and in the lower pressure plate.
